TypeScript Basics

Introduction

TypeScript is JavaScript with static typing. It helps catch many mistakes during development.

Types

Common types include string, number, boolean, array, object, union, and custom types.

Interfaces

Interfaces describe the shape of objects. Example: interface User { name: string; age: number; }

Functions

Function parameters and return values can have explicit types.

React

TypeScript works well with React props, state, event handlers, and API data.

Benefits

Types improve editor support, readability, refactoring, and error detection.

Conclusion

Start by adding types to variables, function parameters, objects, and component props.
